# HW: Week 12

#### 36-350 – Statistical Computing

Week 12 - Fall 2020

Name: Kimberly Zhang

Andrew ID: kyz

You must submit **your own** lab as a knitted PDF file on Gradescope.

This week's homework is a little different. Here you will be working with SQL, specifically with the variant postgres. You will do your work "remotely" in a postgres terminal and cut-and-paste your answers into plain code blocks below:

```
This is a plain code block. Note the lack of a {r} above. Try to avoid issues of text going off the page by utilizing line breaks.
```

Cut-and-paste both your input command and the output. If the output has many rows, it is sufficient to cut-and-paste the first five, unless otherwise instructed.

# Question 1

```
(8 points)
Notes 12A (7-11) + Notes 12B (3)
```

Create a table dubbed rdata that has five columns: id (type serial primary key), a and b (consisting of strings that should be no more than five characters), moment (which is a date), and x (which is a number that should have no more than five digits total and two to the right of the decimal point).

```
create table rdata (
id serial primary key,
a varchar(5),
b varchar(5),
moment date,
x numeric(5,2)
);
```

#### Question 2

```
(8 points)
Notes 12B (4,8)
```

Delete the table and create it again, with certain constraints: a and b cannot be null and must be unique; moment should have a default value of 2020-01-01 (); and x should be larger than zero.

```
drop table rdata;
create table rdata(
id serial primary key,
a varchar(5) unique not null,
```

```
b varchar(5) unique not null,
moment date default '2020-01-01',
x numeric(5,2) check (x > 0)
);
```

# Question 3

```
(8 points)
```

Notes 12A (4)

Use \d in combination with the name of your table to display its properties. Copy and paste all output here.

#### postgres=# \d rdata

Column	<i>J</i> 1	Table "p	Nul		
id   a	<pre>integer character varying(5)</pre>		not   not	null	+    nextval('rdata_id_seq'::regclass) 
moment	character varying(5) date numeric(5,2)		not   	null	   '2020-01-01'::date 
Indexes:					
"rdata_pkey" PRIMARY KEY, btree (id)					
"rdata_a_key" UNIQUE CONSTRAINT, btree (a) "rdata b key" UNIQUE CONSTRAINT, btree (b)					
Check constraints:  "rdata_x_check" CHECK (x > 0::numeric)					

## Question 4

(8 points)

Notes 12B (5)

Insert three rows of data into your table. Do this without explicity referring to the column id or moment. Display your table using the command select \* from rdata. You should see a default date in your moment column!

## Question 5

(8 points)

Notes 12B (5)

Attempt to add another row of data with a negative value for x. Show what happens. (If the row is added...that's bad. It means you don't have the constraint x > 0 defined.) Afterwords, add a valid row of data, and show the table. Is there anything weird?

It is weird that for the new row the id is not 4.

#### Question 6

(8 points)

Notes 12B (6)

Change the table rdata so as to change the data in moment so that two of the dates are in March 2020, while the other two are not in March 2020. Use where as shown in the notes, and utilize a logical "or" to update two of the dates to the same date in March at the same time. Show your updated table. (Note that the rows may be rearranged. This is OK.)

#### Question 7

(8 points)

Notes 12B (7)

Add a new column to rdata dubbed y, and let it be of boolean type with default value false. Display your updated table.

```
1 | x | y | 2020-03-14 | 4.52 | f
5 | g | h | 2020-03-14 | 5.00 | f
(4 rows)
```

## Question 8

```
(8 points)
```

Notes 12B (8)

Remove the row of your table with id value 2. Display your updated table.

#### Question 9

(8 points)

Notes 12B (7)

Rename the column moment to have the name date. Display your updated table.

```
postgres=# alter table rdata rename column moment to date;
ALTER TABLE
```

#### Question 10

(10 points)

Notes 12C (2-4)

Download the file GalaxyStatistics.txt from the DATA directory on Canvas. This file contains three columns: the sky field name, the Gini coefficient value, and the concentration statistic value for each of 8,358 observed galaxies. (Feel free to call the concentration statistic column conc for short.) Copy it into a postgres session to populate a table named galaxies. You should add explicit checks that ensure that gini and conc have values greater than zero. Hint: you'll have to explicitly provide a delimiter value here.

postgres=# \copy galaxies from 'C:\Users\Kimberly Zhang\Documents\36350\Week12\GalaxyStatistics.txt' wi COPY 8358

#### Question 11

(8 points)

Notes 12B (8)

Delete all rows of the table for which the value of gini is less than 0.5 or the value of conc is greater than 3. You should find that 7,883 rows are deleted. (Show this by showing the output of your SQL command.)

postgres=# delete from galaxies where gini < 0.5 or conc > 3; DELETE 7883

# Question 12

```
(10 points)
```

Notes 12B (6-7)

Alter the table to create a new variable cr\_rat that is the ratio of conc to gini. Then display all the rows where the value of cg\_rat is greater than 5.9. (This last part is accomplished by combining select with where in a way that should be hopefully becoming somewhat intuitive.) You should have nine rows of output overall.
